Non-Homogeneous Boundary Value Problems and Applications: Vol. 1 (Grundlehren der mathematischen Wissenschaften) Jacques Louis Lions, Enrico Magenes

1. We describe, at first in a very formal manner, our essential aim. Let m be an open subset of \mathbb{R}^n , with boundary a_m . In m and on a_m we introduce, respectively, linear differential operators P and Q_j , $0 \leq j \leq l$. By "non-homogeneous boundary value problem" we mean a problem of the following type: let f and g_j , $0 \leq j \leq l$, be given in function space S and G , S being a space "on m " and the G 's spaces "on a_m "; we seek u in a function space U "on m " satisfying (1) $Pu = f$ in m , (2) $Q_j u = g_j$ on a_m , $0 \leq j \leq l$. Q_j may be identically zero on part of a_m , so that the number of boundary conditions may depend on the part of a_m considered. 2. We take as "working hypothesis" that, for $f \in S$ and $g_j \in G$, j the problem (1), (2) admits a unique solution $u \in U$, which depends continuously on the data. But for all linear problems, there is a large number of choices for the space U and $\{F; G\}$ (naturally linked together). Generally speaking, our aim is to determine families of spaces U and $\{F; G\}$, associated in a "natural" way with problem (1), (2) and convenient for applications, and also all possible choices for U and $\{F; G\}$ in these families.
